Giant tectonic plate under the Indian Ocean is experiencing a rocky decay ... With you. Within a short time (geologically speaking) this plate will be split in two, a new study finds. For humans, however, this gap will take forever. The plate, known as the India-Australia-Capricorn tectonic plate, breaks down the snail's rate of about 0.06 inches (1.7 millimetres) per year. In other ways, in 1 million years, the two parts of the plate will be about 1 mile (1.7 kilometers) further apart than they are now. It is not a structure that moves fast, but it is still significant compared to other planetary boundaries, said co-researcher Jurell Coudurier-Curveur, a senior scientist at the Marine Geosciences Institute at the Earth Physics Institute in Paris. Related: In photos: The ocean is hidden beneath the Earth's surface for example, the Dead Sea Fault in the Middle East moves about twice as fast, or 0.2 inches (0.4 centimeters) per year, while the San Andreas Fault in California moves about 10 times faster, about 0.7 inches (1.8 cm) per year. The plate splits so slowly and it's still underwater, the researchers almost missed what they call the nascent boundary plate. But two huge clues, two strong earthquakes occurring in a strange place in the Indian Ocean, indicate that the forces changing the Earth were in motion. On April 11, 2012, an earthquake of magnitude 8.6 and magnitude 8.2 occurred near the Indian Ocean near Indonesia. Earthquakes did not occur along the subduction zone, where one tectonic plate slides under another. Instead, these earthquakes originated in a strange place for earthquakes to occur - in the middle of the plate. These earthquakes, as well as other geological evidence, have shown that some kind of deformation occurs far underground, in an area known as the Wharton Basin. This deformation was not entirely unexpected; The India-Australia-Capricorn plate is not a single cohesive unit. Related: Photo Timeline: See how Earth is shaped it's like a puzzle, Coudurier-Curveur told Live Science. It's not one homogeneous dish. There are three plates that are more or less connected to each other and move in the same direction together, she said. A map showing the Wharton Basin, where an 8.6 magnitude and 8.2 magnitude earthquake struck in 2012 (red and white points). Other earthquakes have also occurred in this area over the past few decades, probably due to the new tectonic plate boundary formation there. (Image credit: Coudurier-Curveur, A. et al. Geophysical Research Letters (2020); CC BY 4.0) The team examined a specific fracture zone in the Wharton Basin where the earthquakes occurred. Two sets of data on this area, collected by other scientists on research vessels in 2015 and 2016, showed the topography of the fracture zone. Recording how long it took sound waves to recover from Precipitation of the navy and foundation, the scientists of the ship were able to map the geography of the basin. (Study co-author Satish Singh, Singh, seismology at the Singapore Earth Observatory, led an expedition for the 2015 dataset.) When Kudurier-Krivur and her colleagues looked at two data sets, they found evidence for retractables from each other, which are depressions that occur when a malfunction strike occurs. The most famous wine slip strike is probably the San Andreas fault. These types of faults cause earthquakes when two blocks of the Earth glide past each other horizontally. A good way to visualize this is to put your fists together and then move one forward and the other back. Remarkably, the team found 62 of these retractable pools along the displayed fracture zone, which stretched nearly 217 miles (350 km) in length, though that's probably longer, Kudurier-Kriver said. Some of these pools were huge - up to 1.8 miles (3 km) wide and 5 miles (8 km) long. What's more, the depressions were deeper in the south - as deep as 394 feet (120 meters) - and shallower to the north - as deep as 16 feet (5 m). That could mean that this strike is slipping wine more localized on its southern border, at least for now, Coudurier-Curveur said. The term localized means that shaking occurs at one main fault, compared to the distributed, which is when shaking occurs at several minor faults, she said. These basins, which began to form about 2.3 million years ago, followed a line that ran near the epicenters of the 2012 earthquakes. It doesn't look like it's yet a fully formed plate boundary, William Hawley, a seismologist at Columbia University's Lamont-Doherty Earth Observatory in New York who wasn't involved in the study, told Live Science. But take home the message that it's becoming one, and it probably makes up most of the strain that we know is going on there. This map shows the topography of the seabed and the deformation beneath it at a fracture in the Wharton basin. This fracture most likely formed when the ocean crust was formed, but now this fracture has been turned into a new boundary of the plate. Purple-colored depressions indicate a sliding wine, which is as much a fault as the San Andreas Fault in California. (image credit: Aurelie Coudurier-Curveur; Coudurier-Curveur, A. et al. Geophysical Research Letters (2020); CC BY 4.0)Why is there wine? Kudurier-Krivur noted that the fault zone, weakness in the oceanic crust, is not formed due to earthquakes. Rather, these so-called passive cracks formed, in particular, when the new oceanic crust came out of the mid-ocean ridge (the boundary between the plates where magma comes out) and cracked due to the curvature of the Earth. Now this fracture zone is being repurposed. Nature likes to exploit weaknesses, it likes to use what is already there, Kudurier-Krivur said. Related: Infographic: The highest mountain to the deepest ocean trench while parts of India-Australia-Capricorn are moving at different speeds, this fracture zone, once just a passive crack, becomes a new boundary for the break-up of the plate into two parts, parts, said. However, because the split between India and Australia and Capriation is so slow, another strong earthquake along this particular fault is likely not to occur for another 20,000 years, the researchers say. Moreover, it will take tens of millions of years before the split is completed, Kudurier-Kuiver said. It has long been postulated that these fracture areas of weakness may be the birthplace along which new plate boundaries are formed, such as subduction zones or impact boundaries, said Oliver Jaguz, an associate professor of geology at MIT who was not involved in the study. Anyway, the study reminds us that plate tectonics are constantly moving. The plates are constantly being formed and collapsing on Earth, Jagoutz told Live Science in an email. This is detailed research like these that will allow us to better understand how puzzle plates that make up the earth's outer solid layer formed and evolved. The study was published March 11 in the journal Geophysical Research Letters. Originally published on Live Science.
